### ABSTRACT

A new type of low-temperature  $\text{NH}_3$ -SCR catalyst with a chemical composition of  $\text{Cu}_w\text{Mn}_y\text{Ti}_{1-y}\text{O}_x$  was prepared from layered double hydroxides precursors for the first time. The purpose of this novel design is to improve the  $\text{De-NO}_x$  efficiency and  $\text{SO}_2$  resistance of Mn-based catalysts. The  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst achieved a  $\text{NO}_x$  conversion as high as 90% at 200 °C, which is much higher than that of the control catalysts  $\text{Cu-Mn/TiO}_2$  (86.1%) and  $\text{Mn/TiO}_2$  (80.7%). The properties of catalysts were characterized in detail using a series of physico-chemical techniques including XRD, BET, FTIR, SEM, TEM,  $\text{H}_2$ -TPR,  $\text{NH}_3$ -TPD, TGA, and XPS analyses. The excellent catalytic performance of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst can be associated with its higher specific surface area and surface acidity, and more active  $\text{MnO}_2$  and  $\text{CuO}$  species. Besides, when copper oxide is introduced, the catalysts showed significant resistance to 100 ppm  $\text{SO}_2$  and 5%  $\text{H}_2\text{O}$ . Finally, the poisoning mechanism and the regenerability of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst was proposed. In short, the newly designed  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst was found to have higher catalytic activity and excellent  $\text{SO}_2$  and  $\text{H}_2\text{O}$  resistance compared to the control catalysts of  $\text{Cu-Mn/TiO}_2$  and  $\text{Mn/TiO}_2$ .

### 1. Introduction

In order to fulfill the new and stricter regulations, many pollutant control technologies have been widely used to reduce the emission of air pollutants. The selective catalytic reduction (SCR) of  $\text{NO}_x$  with  $\text{NH}_3$  ( $\text{NH}_3$ -SCR) is an efficient technique for removing  $\text{NO}_x$  from flue gases of power plant [1]. Commercial SCR catalysts (e.g.  $\text{V}_2\text{O}_5\text{-WO}_3\text{/TiO}_2$ ) are always placed prior to dust precipitation and desulphurization system, and the high concentration of  $\text{SO}_2$  and dust normally reduce the performance and durability of catalysts [2]. Therefore, a tail-end configuration is becoming attractive and the development of a suitable catalyst for low temperature (i.e. 140–200 °C) environment is crucial [3].

Over the past decade, great interest has been drawn on the research of low temperature SCR catalysts containing transition metal oxide catalysts such as  $\text{CuO/TiO}_2$ ,  $\text{Fe}_2\text{O}_3\text{/TiO}_2$ , and  $\text{MnO}_x\text{/TiO}_2$  [4–9]. Among them, Mn-based catalysts have shown excellent  $\text{De-NO}_x$  property under low-temperature sulfur-free conditions [10,11]. Under the actual SCR conditions, the stability of sulfates formed on  $\text{TiO}_2$  surface is weaker than that on other supports such as  $\text{ZrO}_2$  and  $\text{Al}_2\text{O}_3$ . Therefore,  $\text{TiO}_2$  is believed to be a more  $\text{SO}_2$ -resistant support than other mixed oxides [12–14]. However,  $\text{Mn/TiO}_2$  catalyst still has some problems, for example, easy sintering, poor thermal stability, and short lifetime, etc.

Especially, during the preparation of  $\text{Mn/TiO}_2$  catalyst, sintering easily occurs, resulting in a poor dispersion of active component. Many studies have shown that the Cu-Ti mixed oxide was a potential catalyst for HC-SCR with excess oxygen [15–19]. In addition, the Cu-based catalysts are more  $\text{SO}_2$ -resistant. Since the conventional impregnation preparation method often results in aggregated Mn oxides and relatively low catalytic activity, thus new synthesis methods for obtaining highly dispersed active components are highly desired.

Layered double hydroxides (LDHs) are a class of ionic lamellar compounds made up of positively charged brucite-like layers, with an interlayer region containing charge compensating anions and solvation molecules. LDHs have been suggested as a promising precursor for the preparation of highly dispersed mixed oxides with many good properties [20–24]. The layered double oxides (LDOs) obtained by calcination of LDHs normally consist highly dispersed active components, which possess better sintering-resistant property [25]. Thus, we propose that by optimizing the chemical composition of catalyst and using LDHs as precursor, a new catalyst  $\text{Cu}_w\text{Mn}_y\text{Ti}_{1-y}\text{O}_x$  containing  $\text{MnO}_x$  and  $\text{CuO}$  as active components and  $\text{TiO}_2$  as support can be designed. And such newly designed SCR catalyst should possess higher catalytic activity and better  $\text{SO}_2$ -resistant and sintering-resistant properties.

In this work,  $\text{Cu}_w\text{Mn}_y\text{Ti}_{1-y}\text{O}_x$  catalysts with different contents of Cu,

Mn, and Ti were prepared from the corresponding LDH precursors. All samples were carefully characterized using a series of techniques including X-ray powder diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), scanning electron microscope (SEM), transmission electron microscopy (TEM), and BET analysis. The NH<sub>3</sub>-SCR catalytic activity of catalysts were evaluated in the range of 100–250 °C. The influence of SO<sub>2</sub> and H<sub>2</sub>O on the performance of catalysts were also investigated and compared with the conventional Mn/TiO<sub>2</sub> and Cu-Mn/TiO<sub>2</sub> catalysts. Finally, the involved mechanism was studied using X-ray photoelectron spectroscopy (XPS), in situ-diffuse reflectance infrared Fourier transform spectroscopy (in situ-DRIFTS), thermogravimetric analysis (TGA), NH<sub>3</sub>-temparature programmed desorption (NH<sub>3</sub>-TPD), SO<sub>2</sub>-temparature programmed desorption (SO<sub>2</sub>-TPD), and H<sub>2</sub>-temparature programmed reduction (H<sub>2</sub>-TPR).

## 2. Experimental

### 2.1. Preparation of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub>

The standard co-precipitation method is used to synthesize the Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs precursors. Hydroxyl ions (OH<sup>−</sup>) and carbonates (CO<sub>3</sub><sup>2−</sup>) were continuously supplied by the decomposition of urea in water. Cu(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O (Sinopharm Chemical Reagent Co., Ltd.), 50% Mn(NO<sub>3</sub>)<sub>2</sub> (Sinopharm Chemical Reagent Co., Ltd.) and titanium propoxide (Alfa Aesar) were used as metal precursors with various ratios of *w* and *y* (*w* = 0.5–3, *y* = 0.25–0.75). The mixed solution was stirred at 90 °C for 2 days. The synthetic precipitate was thoroughly washed with deionized water and then dried at 60 °C for 12 h. Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs were calcined at 400 °C for 5 h to obtain Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>O<sub>x</sub> catalyst. A more detailed preparation process of LDHs has been reported in many literature [26,27]. 20 wt% Mn/TiO<sub>2</sub>, 10 wt% Cu-10 wt% Mn/TiO<sub>2</sub>, 20 wt% Cu-20 wt% Mn/TiO<sub>2</sub>, and 40 wt% Cu-20 wt% Mn/TiO<sub>2</sub> were also prepared using the traditional incipient wetness method as control catalysts.

### 2.2. Catalyst characterization

Powder XRD was used to analyze the synthesized and calcined samples using a reflection mode of Cu Ka radiation on a Shimadzu XRD-7000 instrument. The chemisorption analyzer (SSA-7000, Builder) was used to measure the BET specific surface area (SSA) of samples. The morphologies of samples were characterized using field emission scanning electron microscope (FE-SEM, SU-8010, Hitachi). High resolution transmission electron microscopy (HR-TEM) analyses were performed on Tecnai G2 F20 (FEI, USA), with an accelerating voltage of 200 kV. Thermo Scientific Escalab 250Xi instrument was used for XPS analysis using monochromatic Al *kc* radiation (*hν* = 1486.6 eV) at 15 kW accelerating power. The chemisorption analyzer (PCA-1200, Builder) was used for NH<sub>3</sub>-TPD, SO<sub>2</sub>-TPD, SO<sub>2</sub>+NH<sub>3</sub>+O<sub>2</sub>-TPD, and H<sub>2</sub>-TPR analyses.

Q50 TGA (TA Instruments) was used to perform thermogravimetric analysis of samples. In a flowing nitrogen (60 mL/min), the furnace temperature was raised to 800 °C at a rate of 10 °C/min. The FTS 3000 MX FTIR spectrophotometer (Bruker Vertex 70) was used to perform FTIR analysis using diamond ATR technology. The in situ DRIFT characterization was also implemented on the FTS 3000 MX FTIR (Bruker Vertex 70) spectrophotometer with a reaction cell (ZnSe windows) and a diffuse reflectance attachment (HARRICK). The resolution was 4 cm<sup>−1</sup>, the number of scans was 32, the spectra were expressed as Kubelka–Munk function, and the background spectrum of catalyst was recorded in N<sub>2</sub>.

### 2.3. Catalytic activity measurements

The NH<sub>3</sub>-SCR catalytic experiments of synthesized catalysts were carried out in a fixed-bed stainless steel reactor at a flow rate of

200 mL/min loaded with 150 mg catalyst. The inlet gas contained 500 ppm NH<sub>3</sub>, 500 ppm NO<sub>x</sub> (about 480 ppm NO, and 20 ppm NO<sub>2</sub>), 100 ppm SO<sub>2</sub> (if needed), 5% H<sub>2</sub>O (if needed), and 5% O<sub>2</sub> with Ar as balance. The NO<sub>x</sub> analyzer (Thermo Scientific 42i-HL, USA) was used to monitor the NO<sub>x</sub> concentrations on-line, and the quadrupole mass spectrometer (QGA, Hidden, UK) was used to assess the N<sub>2</sub> selectivity. The NO<sub>x</sub> conversion and N<sub>2</sub> selectivity at the steady state were obtained using the follow Eqs. (1) and (2).

$$\text{NO}_x \text{ conversion} = \left( 1 - \frac{\text{NO}_x(\text{out})}{\text{NO}_x(\text{in})} \right) \times 100\% \quad (1)$$

$$\text{N}_2 \text{ selectivity} = \left( 1 - \frac{2\text{N}_2\text{O}(\text{out})}{\text{NO}_x(\text{in}) + \text{NH}_3(\text{in}) - \text{NO}_x(\text{out}) - \text{NH}_3(\text{out})} \right) \times 100\% \quad (2)$$

## 3. Results and discussion

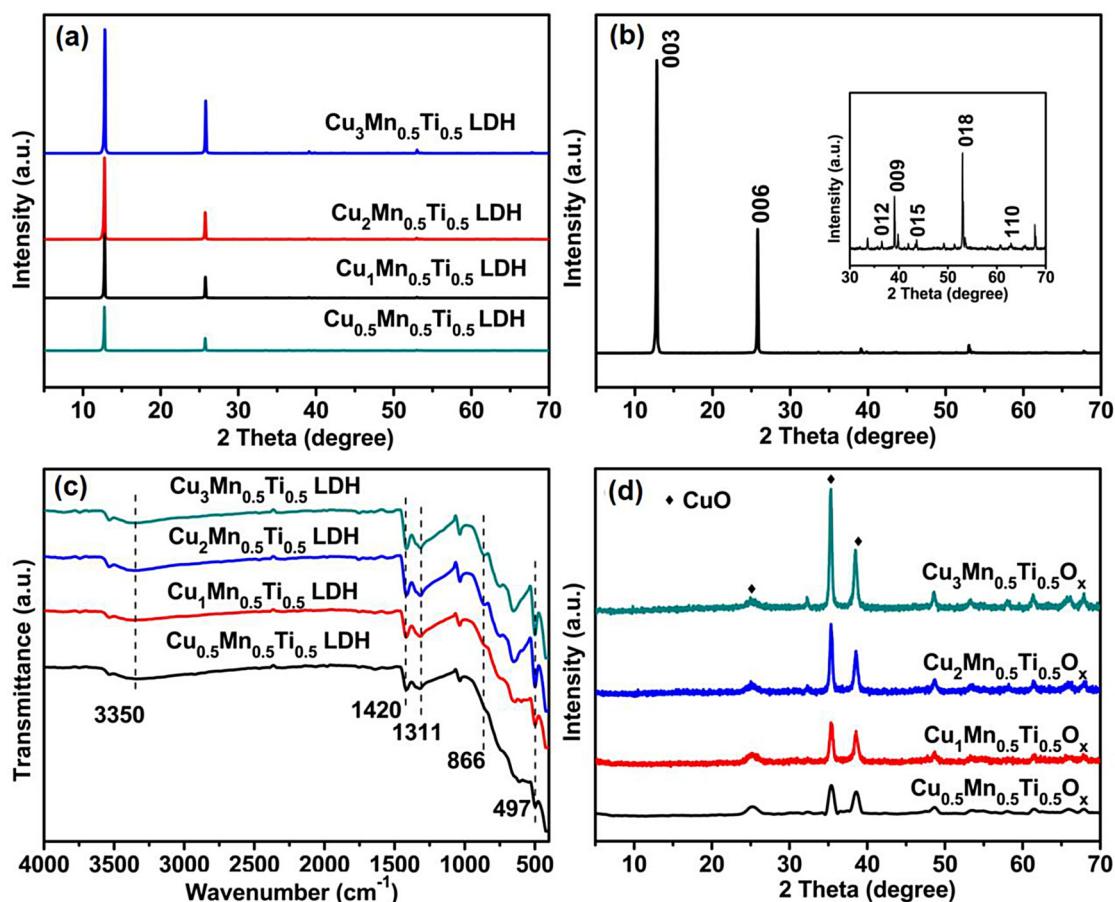

### 3.1. Characterization of samples

First, in order to confirm the successful synthesis of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs, powder XRD analyses were performed. Fig. 1 shows the XRD patterns of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs with the same Mn/Ti of 1 but different Cu/(Mn + Ti) molar ratios of 0.5, 1, 2, and 3. Four precursors all exhibited the characteristic diffraction peaks of LDHs structure without any impurity phase. The diffraction peaks at 2θ = 12.8°, 25.8°, 36.5°, 39.1°, 43.6°, 53.1°, and 63.1° can be attributed to the reflections of (003), (006), (012), (009), (015), (018), and (110) planes for Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs phase, respectively.

The specific surface area (SSA) is an important parameter for the performance of catalysts, thus the BET analyses of LDHs, LDOs, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> were performed and summarized in Table 1. The SSA of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs became higher from 86.6 to 113.5 m<sup>2</sup>/g with the increase in molar ratio of Cu/(Mn + Ti). After calcination, the SSA of obtained mixed oxides were slightly decreased to the range of 56–102.1 m<sup>2</sup>/g. It should be noted that Cu-Mn/TiO<sub>2</sub> catalyst possesses a larger specific surface area than Mn/TiO<sub>2</sub>, indicating that the introduction of copper increased the specific surface area of catalysts [10,28]. Among all mixed oxides, Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> showed the highest SSA. It is well known that higher SSA could provide more available active sites on the catalyst surface for the reactants to participate in the reactions.

In addition, to better illustrate the structure of synthesized Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs, FTIR analyses were further conducted, as shown in Fig. 1(c). All samples exhibited similar FTIR spectra to Mg-Al hydrotalcite. The stretching vibrations of –OH groups at 3350 cm<sup>−1</sup>, the angular deformation vibration of H<sub>2</sub>O molecules at 1420 cm<sup>−1</sup>, and the vibrations of carbonate ions at 1311 cm<sup>−1</sup> were observed. The bands at about 866 and 497 cm<sup>−1</sup> can be attributed to M–O (M–OH, O–M–O or M–O–M) vibrations [21,29–32]. Thus, both XRD and FTIR data confirmed the successful synthesis of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDHs. In addition, after calcination, Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> is mainly present in the CuO phase (Fig. 1(d)), and the related Mn phase almost did not be observed. This is probably because Mn oxide exists in a highly dispersed state.

The morphology of LDHs was revealed by SEM analyses. Fig. 2(a) shows that Cu<sub>0.5</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>CO<sub>3</sub> LDH possesses nanoplatelets morphology assembled together, a typical morphology for LDHs. Fig. 2(b) shows the HR-TEM image of the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst. A lattice fringe with a spacing distance of 0.25 nm was observed, which can be referenced to the (−111) crystal plane of CuO. These data further suggested that Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>CO<sub>3</sub> LDH was successfully synthesized, and thermal treatment can lead to the formation of highly dispersed CuO species, which agrees well with the results of XRD.

**Fig. 1.** (a) XRD patterns of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>-CO<sub>3</sub> LDHs with different Cu/(Mn + Ti) ratios from 0.5 to 3, (b) XRD pattern of Cu<sub>w</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>-CO<sub>3</sub> LDH with Cu/(Mn + Ti) = 1, (c) FTIR spectra of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>-CO<sub>3</sub> LDHs with different Cu/(Mn + Ti) ratios, and (d) XRD patterns of Cu<sub>w</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> LDOs with different Cu/(Mn + Ti) ratios obtained by calcining at 400 °C.

**Table 1**

Specific surface area, pore size, and pore volume of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>-CO<sub>3</sub> LDHs and the corresponding Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>O<sub>x</sub> LDOs.

Samples	BET SSA (m <sup>2</sup> /g)	BH Pore size (Å)	BH pore volume (cm <sup>3</sup> /g)
Cu <sub>0.5</sub> Mn <sub>0.5</sub> Ti <sub>0.5</sub> CO <sub>3</sub> LDH	86.6	46.0	0.199
Cu <sub>1</sub> Mn <sub>0.5</sub> Ti <sub>0.5</sub> CO <sub>3</sub> LDH	113.5	71.8	0.408
Cu <sub>2</sub> Mn <sub>0.5</sub> Ti <sub>0.5</sub> CO <sub>3</sub> LDH	99.8	46.3	0.231
Cu <sub>3</sub> Mn <sub>0.5</sub> Ti <sub>0.5</sub> CO <sub>3</sub> LDH	68.3	45.2	0.154

Cu <sub>2</sub> Mn <sub>0.5</sub> Ti <sub>0.5</sub> O <sub>x</sub> LDO	83.2	79.6	0.331
Cu <sub>3</sub> Mn <sub>0.5</sub> Ti <sub>0.5</sub> O <sub>x</sub> LDO	56.0	54.7	0.153
Mn/TiO <sub>2</sub>	34.3	56.3	0.112
Cu-Mn/TiO <sub>2</sub>	45.1	63.6	0.104

### 3.2. NH<sub>3</sub>-SCR activity of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>O<sub>x</sub> catalysts

#### 3.2.1. The effect of catalyst components

To further investigate the role of catalyst components in Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>O<sub>x</sub> catalysts with different molar ratios of Cu/(Mn + Ti) and Mn/Ti were prepared and catalytically evaluated. Fig. 3 presents the influences of Cu/(Mn + Ti) ratio (0.5, 1, 2, and 3) and Mn/Ti ratio (1:3, 1:1, and 3:1) on the De-NO<sub>x</sub> activity of Cu<sub>w</sub>Mn<sub>y</sub>Ti<sub>1-y</sub>O<sub>x</sub> catalysts in the low temperature range of 100–250 °C. Initially, we optimized the Cu/(Mn + Ti) molar ratio of Cu<sub>w</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> by varying the Cu/(Mn + Ti) ratio from 0.5 to 1, 2, and 3. It could be seen that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> represents the best SCR catalyst, with a De-NO<sub>x</sub> up to 90% at 200 °C.

The effect of Mn/Ti molar ratio (1:3, 1:1 and 3:1) was also

investigated after determining the optimal Cu/(Mn + Ti), as shown in Fig. 3(b). The NO<sub>x</sub> conversions increased obviously by increasing the Mn/Ti molar ratio from 1:3 to 1:1 at 100–250 °C. However, the NO<sub>x</sub> conversion decreased for a certain extent with a further increase of Mn/Ti ratio from 1:1 to 3:1. For instance, at 100, 150, 200, and 250 °C, the NO<sub>x</sub> conversion was decreased from 52.2%, 78.4%, 90%, and 80.8% to 30.9%, 51.1%, 80.8%, and 70.3%, respectively. It is well known that when the loading exceeds the maximum loading of the support monolayer, sintering will occur, thereby resulting in a decrease in the NO<sub>x</sub> conversion. These data clearly demonstrated that the Cu/(Mn + Ti) and Mn/Ti molar ratios had a significant influence on the De-NO<sub>x</sub> activity of catalysts, and the optimum composition Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> exhibited the highest NO<sub>x</sub> conversion of 90% at 200 °C.

In the following section, a comparative study on Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts was performed, as shown in Fig. 4. It can be seen that the performance of Mn/TiO<sub>2</sub> and Cu-Mn/TiO<sub>2</sub> was worse than that of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst within the whole experimental temperature range. The low temperature activities of Cu-Mn/TiO<sub>2</sub> and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts, with the introduction of Cu, were significantly better than that of Mn/TiO<sub>2</sub> catalyst. For Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, the NO<sub>x</sub> conversion at 200 °C was 80.7%, 86.1%, and 90%, respectively. It is apparent that the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst possessed much better SCR performance than the other two catalysts. In addition, the selectivity of NO<sub>x</sub> conversion into N<sub>2</sub> was also investigated over Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts, as shown in Fig. 4(a). The N<sub>2</sub> selectivity of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> was 99.4%, which is much higher than that of Cu-Mn/TiO<sub>2</sub> (95%) and Mn/TiO<sub>2</sub> (88%) at 200 °C. Thus, it can be concluded that the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst not only possesses high De-NO<sub>x</sub>

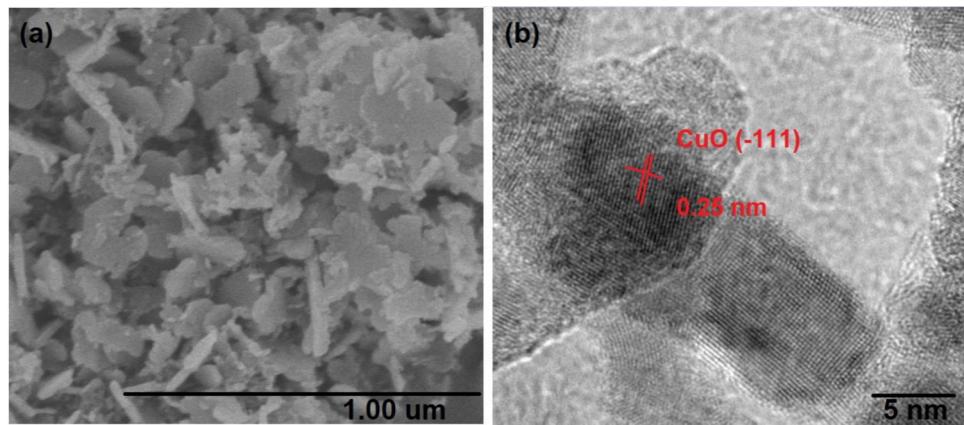

Fig. 2. (a) SEM image of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{-CO}_3$  LDH, and (b) the HR-TEM image of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  calcined at 400 °C.

property, but also has high  $\text{N}_2$  selectivity.

More control catalysts with higher Cu and Mn loadings, 20 wt% Cu-20 wt% Mn/TiO<sub>2</sub> and 40 wt% Cu-20 wt% Mn/TiO<sub>2</sub>, were also synthesized and evaluated. As shown in Fig. S2, the  $\text{NO}_x$  conversion decreased with increasing the loadings of Cu and Mn, which was 86.1%, 80.2%, and 60.3% for 10 wt% Cu-10 wt% Mn/TiO<sub>2</sub>, 20 wt% Cu-20 wt% Mn/TiO<sub>2</sub>, and 40 wt% Cu-20 wt% Mn/TiO<sub>2</sub>, respectively. This is due to the maximum monolayer load limitation of the carrier. However,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  showed higher  $\text{NO}_x$  conversion of 90% under the same condition. These results demonstrated that the catalysts obtained by calcination of LDHs can avoid the maximum monolayer load limitation of the carrier, and thereby obtaining highly dispersed catalysts with improved catalytic activity.

To clarify why  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst has better activity than conventional catalysts, the XRD patterns of samples were analyzed and displayed in Fig. 4(b). After 400 °C calcination, both Mn/TiO<sub>2</sub> and Cu-Mn/TiO<sub>2</sub> were converted into a mixture of oxides and spinels. For Mn/TiO<sub>2</sub>, the diffraction peaks can be attributed to anatase TiO<sub>2</sub> and crystallized MnO<sub>2</sub> (JCPDS No. 24-0735). For Cu-Mn/TiO<sub>2</sub>, there were some new peaks corresponded to CuO phase (JCPDS No. 48-1548). For  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , only CuO phase (JCPDS No. 48-1548) was observed, while the MnO<sub>x</sub> phase was not identified. It implies that the manganese oxides might be in a highly dispersed state.

In order to identify the chemical composition and the state of surface species of different catalysts, the samples were examined using XPS analyses. The photoelectron spectra of O 1 s, Cu 2p, and Mn 2p of Mn/TiO<sub>2</sub>,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , and Cu-Mn/TiO<sub>2</sub> samples were displayed in Fig. 5. The XPS spectra of Cu 2p for  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  and Cu-Mn/TiO<sub>2</sub> catalysts were displayed in Fig. 5(a). For these two catalysts, the Cu 2p<sub>3/2</sub> and Cu 2p<sub>1/2</sub> peaks at 934 and 955.0 eV were observed, with two satellite peaks at 960.0–965.0 eV and 938.0–945.0 eV, respectively. The value of  $\text{Cu}^{2+}/(\text{Cu}^{2+} + \text{Cu}^{1+})$  in  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  (63%) is higher than that in Cu-Mn/TiO<sub>2</sub> (49.4%), which is beneficial for promoting the

low-temperature SCR activity.

The XPS spectra of Mn 2p for Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, and  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalysts were displayed in Fig. 5(b), which suggests that MnO<sub>x</sub> existed as a mixed-valence state in these three catalysts. The value of  $\text{Mn}^{4+}/(\text{Mn}^{4+} + \text{Mn}^{3+})$  follows the order of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  (53.4%) > Cu-Mn/TiO<sub>2</sub> (48.6%) > Mn/TiO<sub>2</sub> (38.0%). Previous studies have demonstrated that the presence of Mn<sup>4+</sup> species is conducive to the low temperature De- $\text{NO}_x$  activity [25,33–35]. Therefore, the higher value of  $\text{Mn}^{4+}/(\text{Mn}^{4+} + \text{Mn}^{3+})$  in  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst may be one of the reasons for its higher catalytic activity at low temperature.

In Fig. 5(c), all Ti 2p XPS spectra consist two peaks at 464.3 and 458.3 eV, which represent Ti 2p<sub>1/2</sub> and Ti 2p<sub>3/2</sub>. The result also indicated that Ti<sup>4+</sup> state is the main valence in all catalysts [36,37]. After introducing Cu, the binding energies shifted to lower values. This indicated that the introduction of Cu can influence the chemical environments of Ti<sup>4+</sup> in Cu-Mn/TiO<sub>2</sub> and  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalysts.

The O 1 s XPS spectra of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> catalysts were displayed in Fig. 5(d), which could be fitted into two peaks. The peak at 528.7–530.9 eV corresponds to lattice oxygen (O<sub>α</sub>), whereas the other peak at 531.4–532.5 eV is related to the surface adsorbed oxygen (O<sub>β</sub>) [38]. It has been reported that O<sub>β</sub> has an important influence on the oxidation reaction due to its higher mobility [39–41]. The O<sub>β</sub>/(O<sub>α</sub> + O<sub>β</sub>) ratios of Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> catalysts were significantly lower than that of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  sample. XPS results indicated that the relatively higher ratios of  $\text{Cu}^{2+}/(\text{Cu}^{2+} + \text{Cu}^{1+})$ ,  $\text{Mn}^{4+}/(\text{Mn}^{4+} + \text{Mn}^{3+})$ , and O<sub>β</sub>/(O<sub>α</sub> + O<sub>β</sub>) might account for the good De- $\text{NO}_x$  performance of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst.

The FTIR spectroscopy of pyridine chemisorption is most widely used to detect the surface acidity of catalysts. Fig. 6(a) shows the FTIR spectra of pyridine adsorbed on Mn/TiO<sub>2</sub>,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , and Cu-Mn/TiO<sub>2</sub>. The bands at about 1446, 1490, 1577, and 1597  $\text{cm}^{-1}$  can be attributed to the pyridine coordinated to L acids, whereas the characteristic band at 1546  $\text{cm}^{-1}$  corresponds to B acid sites [42]. The

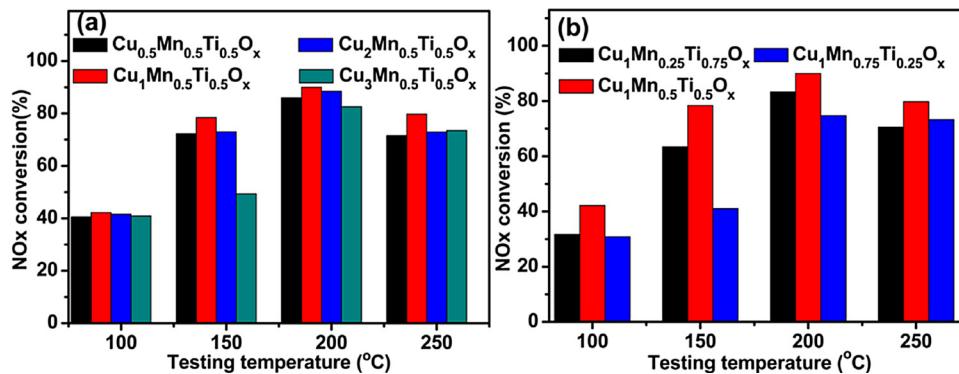

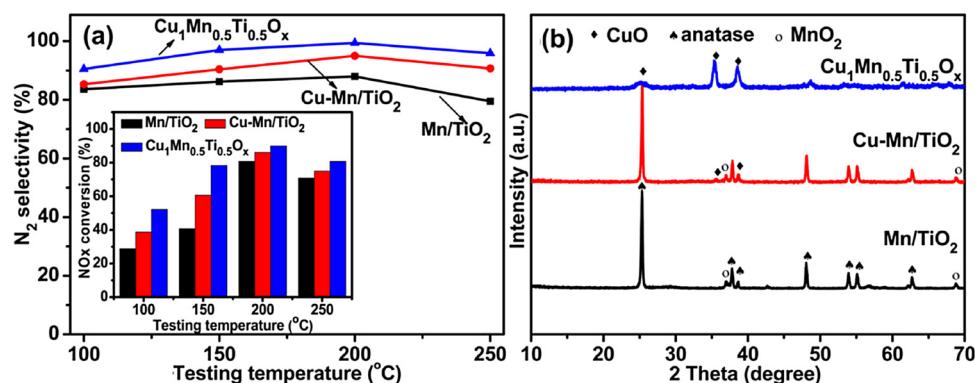

Fig. 3. The influence of (a) Cu/(Mn + Ti) ratio (0.5, 1, 2, and 3), (b) Mn/Ti ratio (1:3, 1:1, and 3:1) on the activity of  $\text{Cu}_w\text{Mn}_y\text{Ti}_{1-y}\text{O}_x$  mixed oxide catalysts. Calcination temperature = 400 °C, and operating temperature = 100, 150, 200, and 250 °C. Reaction conditions:  $[\text{NO}_x] = [\text{NH}_3] = 500 \text{ ppm}$ ,  $[\text{O}_2] = 5\%$ , balance Ar, total flow rate = 200 mL/min, catalyst 0.15 g.

**Fig. 4.** (a) The  $\text{NO}_x$  conversion and  $\text{N}_2$  selectivity over  $\text{Mn}/\text{TiO}_2$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalysts, and (d) The XRD patterns of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Mn}/\text{TiO}_2$  calcined at 400 °C. Reaction conditions:  $[\text{NO}_x] = [\text{NH}_3] = 500 \text{ ppm}$ ,  $[\text{O}_2] = 5\%$ , balance Ar, total flow rate = 200 mL/min, catalyst 0.15 g.

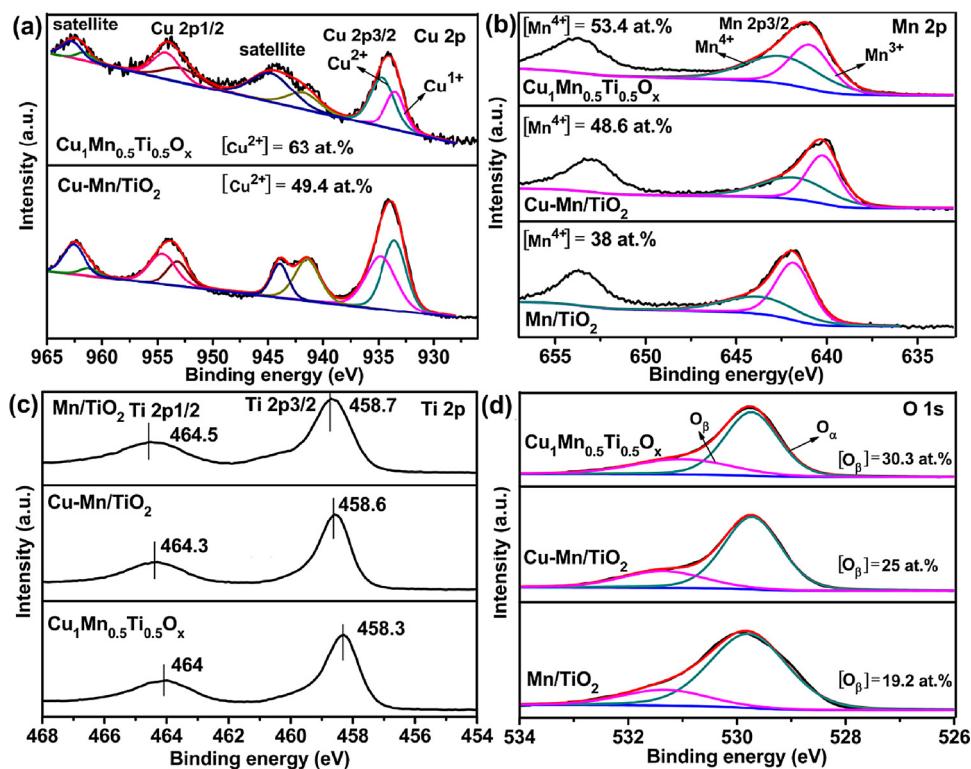

concentrations of the L and B sites can be quantified from the intensities of the peaks at about 1450 and 1546  $\text{cm}^{-1}$ , which follows the order of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  (230.5  $\mu\text{mol/g}$ ) >  $\text{Cu}-\text{Mn}/\text{TiO}_2$  (127.2  $\mu\text{mol/g}$ ) >  $\text{Mn}/\text{TiO}_2$  (102.1  $\mu\text{mol/g}$ ) [43,44]. Fig. 6(b) shows the relationship between the catalytic performance and acidity. Obviously, with the introduction of Cu, the catalytic performance of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst increases with elevating the quantities of L and B acids.

The surface acidity and surface Cu and Mn active species of  $\text{Mn}/\text{TiO}_2$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{CuMnTiO}_x$  catalysts were investigated by  $\text{NH}_3$ -TPD and  $\text{H}_2$ -TPR experiments, as shown in Fig. 6(c, d). Since the adsorption of  $\text{NH}_3$  is very important in  $\text{NH}_3$ -SCR reaction,  $\text{NH}_3$ -TPD analysis was used to determine the catalyst surface acidity. Two desorption peaks for all samples were observed, which can be described as the reduction of  $\text{MnO}_x$  and/or copper species. The desorption peak at low temperature located at about 155 °C. The amounts of desorbed  $\text{NH}_3$  (surface acidity) were compared by integrating the  $\text{NH}_3$ -TPD curves and it is obvious that  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  possesses much higher intensity than that of  $\text{Mn}/\text{TiO}_2$  and  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , indicating  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  has more

acidic sites for  $\text{NH}_3$  adsorption. The reaction mechanism of  $\text{NH}_3$ -SCR has been previously investigated and it has been demonstrated that the catalytic property is related to the surface acidity of catalysts [45].

According to literature report, the reduction peak of  $\text{Mn}/\text{TiO}_2$  catalyst between 150 and 500 °C could be divided into three steps:  $\text{MnO}_2 \rightarrow \text{Mn}_2\text{O}_3 \rightarrow \text{Mn}_3\text{O}_4 \rightarrow \text{MnO}$  [46]. For  $\text{Cu}-\text{Mn}/\text{TiO}_2$ ,  $\text{Cu}_{0.5}\text{Mn}_{0.5}\text{O}_x$ ,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ ,  $\text{Cu}_2\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , and  $\text{Cu}_3\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  samples, three reduction peaks were observed, which related to the stepwise reduction of  $\text{CuO}_x$  species i.e.,  $\text{Cu}^{2+} \rightarrow \text{Cu}^{1+}$  (about 136 °C) and  $\text{Cu}^{1+} \rightarrow \text{Cu}$  (about 163 °C) [47], and the bulk  $\text{Cu}^{2+}$  reduction [48], overlapped with the reduction of surface  $\text{MnO}_x$  species. For  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , in addition to the reduction peak at about 250 °C, actually there was one peak at around 146 °C for the reduction of Cu. However, because the peak was so weak that after being combined with other data, this peak became not so obvious. In order to prevent any misleading, we provided the  $\text{H}_2$ -TPR profile of  $\text{Cu}-\text{Mn}/\text{TiO}_2$  catalyst separately as Fig. S1.

For  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , the intensity of  $\text{H}_2$ -TPR at low temperature was stronger than that of  $\text{Cu}-\text{Mn}/\text{TiO}_2$  and  $\text{Mn}/\text{TiO}_2$ , suggesting that

**Fig. 5.** XPS spectra of (a) Cu 2p, (b) Mn 2p, (c) Ti 2p, and (d) O 1s of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Mn}/\text{TiO}_2$  catalysts.

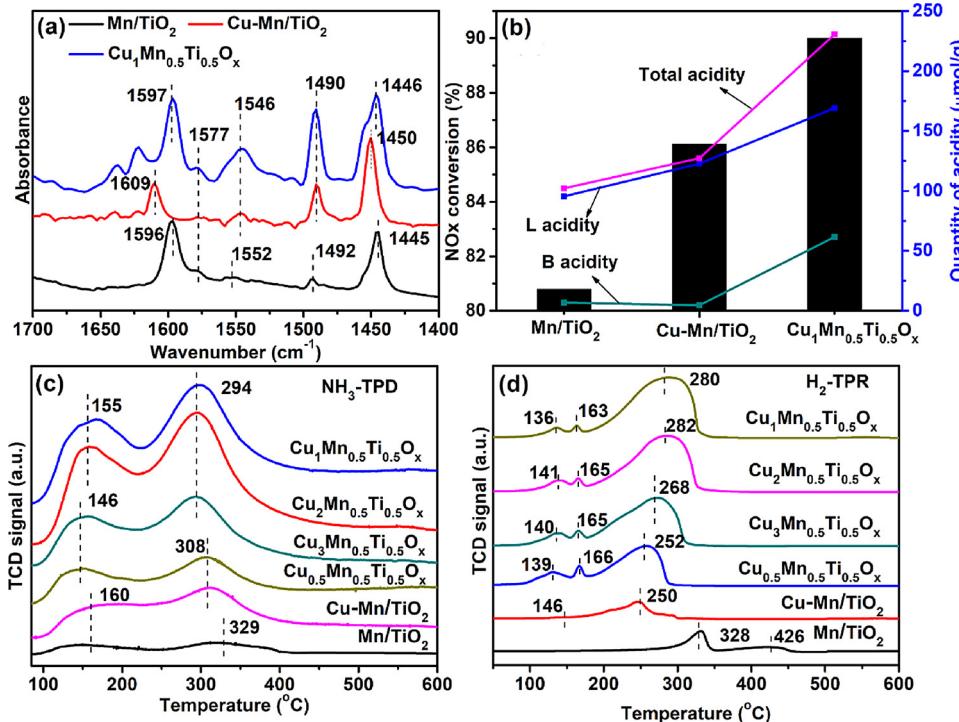

Fig. 6. (a) FTIR spectra of pyridine adsorbed at 200 °C on Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> catalysts, (b) Variations in the quantity of acidity and the catalytic performance of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> catalysts at 200 °C, (c) NH<sub>3</sub>-TPD and (d) H<sub>2</sub>-TPR profiles over the Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu<sub>2</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu<sub>3</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu<sub>0.5</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, and Cu-Mn/TiO<sub>2</sub> catalysts.

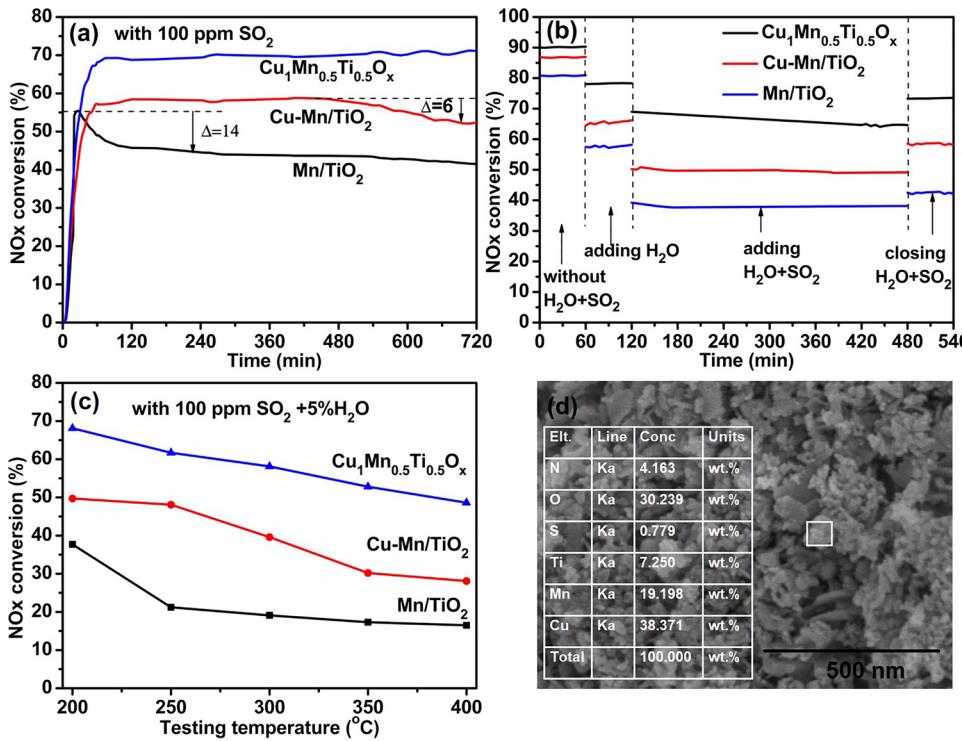

Fig. 7. (a) Long-term isothermal NO<sub>x</sub> conversion of catalysts in the presence of 100 ppm SO<sub>2</sub> at 200 °C, (b) The influence of 5% H<sub>2</sub>O and 100 ppm SO<sub>2</sub> addition on the NO<sub>x</sub> conversion of catalysts at 200 °C, (c) The influence of 5% H<sub>2</sub>O and 100 ppm SO<sub>2</sub> on the NO<sub>x</sub> conversion of catalysts at different temperature, and (d) SEM image of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> after used in the gas containing 5% H<sub>2</sub>O and 100 ppm SO<sub>2</sub> at 200 °C. The inset Table is the SEM-EDX analysis of the selected area of sample. Reaction conditions: [NO<sub>x</sub>] = [NH<sub>3</sub>] = 500 ppm, [O<sub>2</sub>] = 5%, [H<sub>2</sub>O] = 5%, [SO<sub>2</sub>] = 100 ppm, balance Ar, total flow rate = 200 mL/min, catalyst 0.15 g.

Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> surface possesses more highly dispersed copper and manganese oxide crystallites, which are important active species for the low-temperature SCR reaction. Therefore, the increase of surface active species on Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> maybe one reason for its higher NO<sub>x</sub> conversion than the conventional Mn/TiO<sub>2</sub> catalyst. The H<sub>2</sub>-TPR peak areas of Cu-Mn/TiO<sub>2</sub> and CuMnTiO<sub>x</sub> are larger than that of Mn/TiO<sub>2</sub>. The H<sub>2</sub> consumptions of samples were quantified through a pulse experiment, which followed the sequence of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> (1.15 mmol/g) > Cu<sub>2</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> (0.82 mmol/g) > Cu<sub>3</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> (0.69 mmol/g) > Cu<sub>0.5</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> (0.47 mmol/g) > Cu-Mn/TiO<sub>2</sub> (0.25 mmol/g) > Mn/TiO<sub>2</sub> (0.16 mmol/g). The improvement maybe attributed to the synergistic influence between copper and manganese species. Therefore, Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> prepared by LDH calcination has higher Mn and Cu species reduction ability, which means that the surface oxygen mobility increases and the SCR reaction proceeds rapidly [20,49].

g) > Mn/TiO<sub>2</sub> (0.16 mmol/g). The improvement maybe attributed to the synergistic influence between copper and manganese species. Therefore, Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> prepared by LDH calcination has higher Mn and Cu species reduction ability, which means that the surface oxygen mobility increases and the SCR reaction proceeds rapidly [20,49].

### 3.2.2. The effect of SO<sub>2</sub> and H<sub>2</sub>O

SO<sub>2</sub> poisoning is a critical problem for SCR catalysts. As shown in Fig. 7(a), the long-term De-NO<sub>x</sub> properties of Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts were evaluated at 200 °C with 100 ppm

**Table 2**

Specific surface area, pore size, and pore volume of fresh and sulfated  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Mn}/\text{TiO}_2$ .

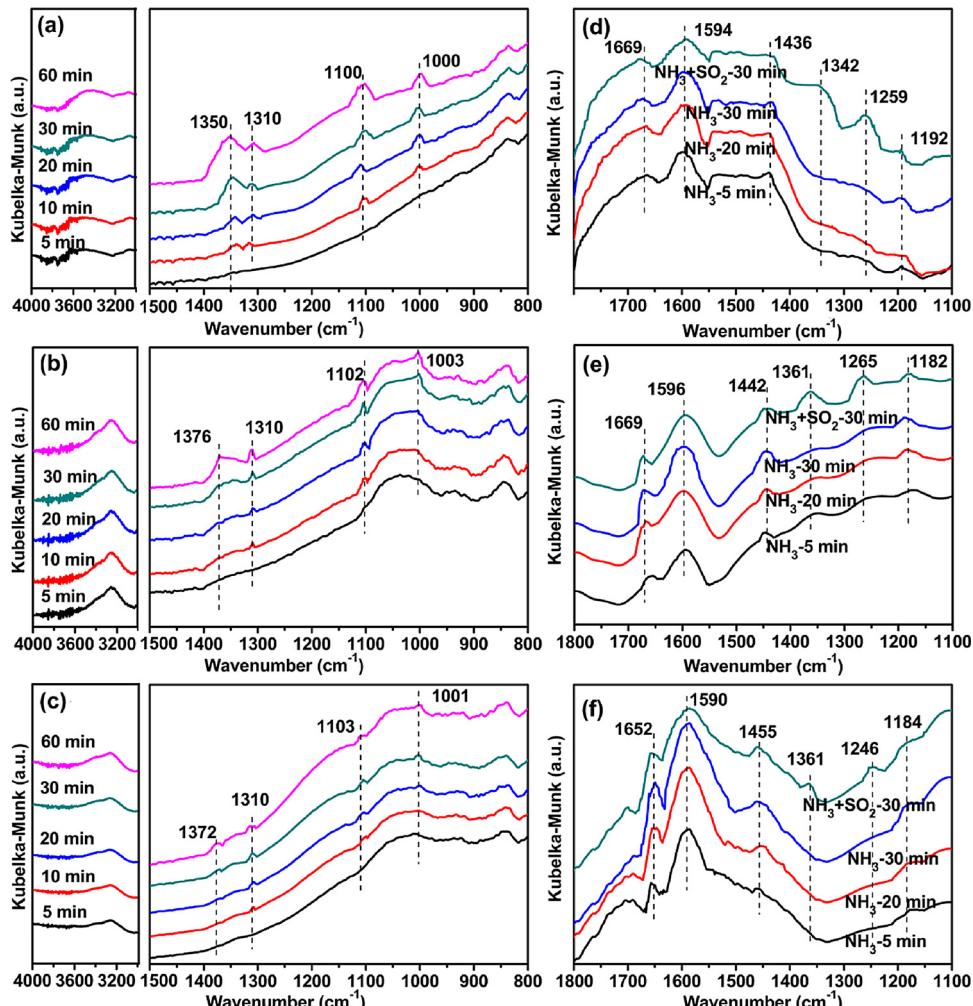

Samples	BET SSA ( $\text{m}^2/\text{g}$ )	BJH Pore size (Å)	BJH pore volume ( $\text{cm}^3/\text{g}$ )
$\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$	102.1	66.3	0.339
$\text{Cu}-\text{Mn}/\text{TiO}_2$	45.1	63.6	0.104
$\text{Mn}/\text{TiO}_2$	34.3	56.3	0.112
$\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x\text{-S}$	69.3	49.8	0.173
$\text{Cu}-\text{Mn}/\text{TiO}_2\text{-S}$	26.4	139.8	0.115
$\text{Mn}/\text{TiO}_2\text{-S}$	16.4	127.7	0.104

$\text{SO}_2$ . For  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  sample, the  $\text{NO}_x$  conversion only slightly decreased even after running for 12 h. However, the decreases in  $\text{NO}_x$  conversion for  $\text{Mn}/\text{TiO}_2$  and  $\text{Cu}-\text{Mn}/\text{TiO}_2$  were significant, which was 14% and 6% respectively after 10 h. These results clearly demonstrated that  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  sample is much less effected by  $\text{SO}_2$  than  $\text{Mn}/\text{TiO}_2$  and has great potential for practical applications.

For low-temperature  $\text{NH}_3\text{-SCR}$ , the influences of  $\text{H}_2\text{O}$  and  $\text{SO}_2$  on the De- $\text{NO}_x$  performance can not be ignored [50,51]. Thus, the resistance of  $\text{Mn}/\text{TiO}_2$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalysts to both  $\text{H}_2\text{O}$  and  $\text{SO}_2$  was also investigated at 200 °C, as displayed in Fig. 7(b). Without  $\text{H}_2\text{O}$  and  $\text{SO}_2$ , the  $\text{NO}_x$  conversion for  $\text{Mn}/\text{TiO}_2$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  was 80%, 86%, and 90%, respectively. After adding

5%  $\text{H}_2\text{O}$ , the  $\text{NO}_x$  conversion of  $\text{Mn}/\text{TiO}_2$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  decreased to 58%, 66.1% and 78.3%, respectively. After adding 5%  $\text{H}_2\text{O}$  and 100 ppm  $\text{SO}_2$  simultaneously, the synergistic influence of  $\text{H}_2\text{O}$  and  $\text{SO}_2$  further decreased the catalysts property. However,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  still resulted in higher activity than  $\text{Mn}/\text{TiO}_2$  and  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , even with both  $\text{H}_2\text{O}$  and  $\text{SO}_2$ . For  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ , the  $\text{NO}_x$  conversion was still 64.6% after 6 h, which is much higher than that for  $\text{Mn}/\text{TiO}_2$  (38.0%) and  $\text{Cu}-\text{Mn}/\text{TiO}_2$  (49.1%). Once  $\text{H}_2\text{O}$  and  $\text{SO}_2$  were stopped, the  $\text{NO}_x$  conversion for  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  recovered to 73.4%, and the conversion of  $\text{Mn}/\text{TiO}_2$  and  $\text{Cu}-\text{Mn}/\text{TiO}_2$  was only recovered to 42.1% and 58.1%, respectively. This results indicated that  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst also possesses better resistance to the coexistence of  $\text{SO}_2$  and  $\text{H}_2\text{O}$  than  $\text{Mn}/\text{TiO}_2$  and  $\text{Cu}-\text{Mn}/\text{TiO}_2$  catalysts.

In order to observe the viability of catalysts, the effect of 100 ppm  $\text{SO}_2$  and 5%  $\text{H}_2\text{O}$  at higher temperatures (200–400 °C) of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$ ,  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and  $\text{Mn}/\text{TiO}_2$  catalysts were comparatively examined, as shown in Fig. 7(c). With the increase of testing temperature, the catalytic property of all catalysts showed a certain degree of decline.  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalyst showed higher catalytic property in the whole tested temperature range. For instance, at 250 °C,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  resulted in a  $\text{NO}_x$  conversion of 61.7%, which is much higher than that for  $\text{Cu}-\text{Mn}/\text{TiO}_2$  (48.1%) and  $\text{Mn}/\text{TiO}_2$  (21.2%). At 400 °C, the  $\text{NO}_x$  conversion of  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  decreased to 48.6%, but it was still higher than that of  $\text{Cu}-\text{Mn}/\text{TiO}_2$  (28.1%) and  $\text{Mn}/\text{TiO}_2$

**Fig. 8.** In situ DRIFT 500 ppm  $\text{SO}_2$  + 5%  $\text{O}_2$  co-adsorption spectra over (a)  $\text{Mn}/\text{TiO}_2$  (b)  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and (c)  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalysts at 200 °C as a function of time for 60 min. In situ DRIFT spectra obtained after a 30 min exposure to 1000 ppm  $\text{NH}_3$  and 1000 ppm  $\text{NH}_3$  + 500 ppm  $\text{SO}_2$  in the presence of 5%  $\text{O}_2$  over (d)  $\text{Mn}/\text{TiO}_2$ , (e)  $\text{Cu}-\text{Mn}/\text{TiO}_2$ , and (f)  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  catalysts at 200 °C.

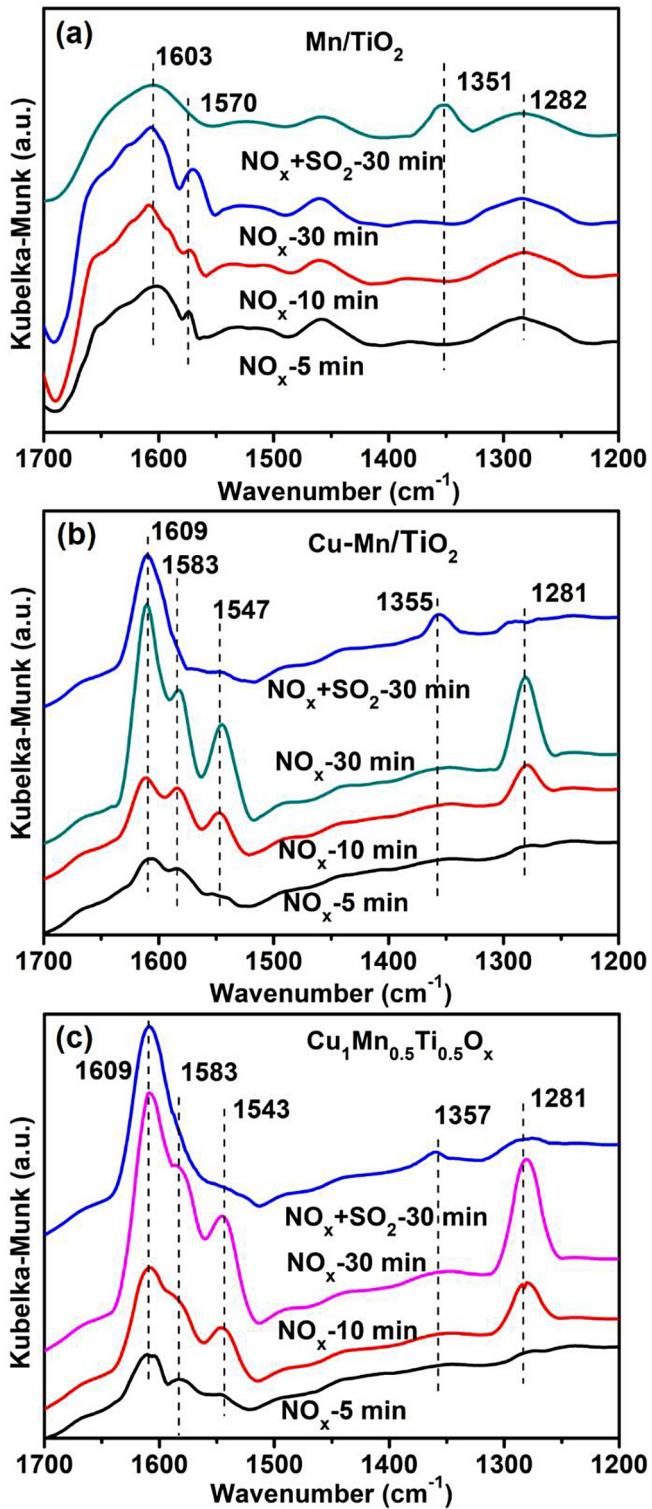

Fig. 9. In situ DRIFT spectra obtained after a 30 min exposure to 2000 ppm NO + 5% O<sub>2</sub> or 2000 ppm NO + 500 ppm SO<sub>2</sub> in the presence of 5% O<sub>2</sub> over (a) Mn/TiO<sub>2</sub>, (b) Cu-Mn/TiO<sub>2</sub>, and (c) Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts at 200 °C.

(16.5%). In all, the results suggested that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has better viability and stability, even at higher temperatures and in the presence of SO<sub>2</sub> and H<sub>2</sub>O.

The used catalysts were further characterized using XRD and SEM analyses. In the XRD patterns of Fig. S3, no characteristic diffraction peak of the sulfate species was found. This may be due to the short time of SO<sub>2</sub> poisoning and the low content of sulfate species. We then

examined the morphology of the used Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> by SEM characterization, as shown in Fig. 7(d). Some deposits could be seen on the surface, which may be attributed to the formation of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>/NH<sub>4</sub>HSO<sub>4</sub> and sulfate species. To further confirm the existence of sulfate species, SEM-EDS analysis was performed as shown in the inset of Fig. 7(d), which indicated that the sulfate species indeed existed on the surface of catalyst, although the amount was quite small.

In addition, the SSA of fresh and deactivated catalysts are summarized in Table 2. The SSA of fresh Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> was 102.1, 45.1, and 34.3 m<sup>2</sup>/g, respectively. After the sulfate species formed and deposited on the catalysts surface, the SSA of all sulfated Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> became 69.3, 26.4, and 16.4 m<sup>2</sup>/g, respectively. Obviously, the SSA of all samples decreased to a certain extent, which may be one reason to explain the decrease in catalytic activity. However, it is apparent that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> also possesses larger SSA than other catalysts. The BET analyses also confirmed that the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst has stronger resistance to SO<sub>2</sub> than the other controlled catalysts.

The DRIFT experiment of SO<sub>2</sub> + O<sub>2</sub> at 200 °C was used to understand the inter-relationship between catalysts and sulfates. As displayed in Fig. 8, the symmetric stretching frequencies of O—S—O species at about 1000 and 1100 cm<sup>-1</sup>, and the asymmetric stretching frequencies of O=S=O species at about 1310 and 1350 cm<sup>-1</sup> were detected [49,52,53]. However, the band at 1350 cm<sup>-1</sup> on Mn/TiO<sub>2</sub> was much stronger than that on Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, indicating that much more sulfates species was formed on Mn/TiO<sub>2</sub>. The results showed that the formation of sulfate species is due to sulfation at 200 °C, while Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has better resistance to SO<sub>2</sub> than Mn/TiO<sub>2</sub>.

NH<sub>3</sub> adsorption is believed to be an important step in NH<sub>3</sub>-SCR reaction. Therefore in order to clarify how SO<sub>2</sub> might impact this process, a comparative study was performed. Fig. 8(d-f) displays the DRIFT spectra of Cu-Mn/TiO<sub>2</sub>, Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, and Mn/TiO<sub>2</sub> after exposure to NH<sub>3</sub>/N<sub>2</sub> and SO<sub>2</sub> co-adsorption with NH<sub>3</sub> at different times. The bands at 1590–1596 cm<sup>-1</sup> and 1182–1192 cm<sup>-1</sup> belong to NH<sub>3</sub> coordinated to L acids [52,54]. The bands at 1652–1669 cm<sup>-1</sup> and 1436–1455 cm<sup>-1</sup> assigned to B acids [55]. However, for Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, the intensity of band at 1590 and 1652 cm<sup>-1</sup> was much stronger than that on other catalysts, indicating a stronger adsorption of NH<sub>3</sub> due to the addition of Cu. This NH<sub>3</sub>-DRIFT conclusion is consistent with the pyridine infrared and NH<sub>3</sub>-TPD conclusions, suggesting that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has more L and B acid sites, and may be one of the reasons for its high activity.

All catalysts were then exposed to both NH<sub>3</sub> and SO<sub>2</sub> for 30 min. Compared with only NH<sub>3</sub> exposure, the intensity of bands corresponding to NH<sub>3</sub> on L acid sites (about 1590 cm<sup>-1</sup>) and B acid sites (1652 cm<sup>-1</sup>) slightly decreased, which indicated that the amount of adsorbed NH<sub>3</sub> on L and B acid sites was reduced. However, the emergence of new bands at 1342–1361 cm<sup>-1</sup> and 1246–1265 cm<sup>-1</sup> suggested the formation of O=S=O and HSO<sub>4</sub><sup>-</sup> species, respectively [49]. These results showed that SO<sub>2</sub> indeed has an impact on NH<sub>3</sub> adsorption, and forms some new NH<sub>4</sub>HSO<sub>4</sub> species. Notably, it is clear that during SO<sub>2</sub> co-adsorption with NH<sub>3</sub>, Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> still has more L acid sites and less NH<sub>4</sub>HSO<sub>4</sub> species compared with other catalysts, which is very important for the occurrence of SCR reactions.

In order to better explain the formation of NO<sub>2</sub> in the mechanism scheme, an NO + O<sub>2</sub> adsorption experiment on in situ DRIFT was performed. For the NO + O<sub>2</sub> adsorption experiments, 2000 ppm NO + 5% O<sub>2</sub> was injected for 30 min at 200 °C and the corresponding spectra were recorded as a function of time. As shown in Fig. 9, the formation of bands at about 1609, 1583, 1543, and 1281 cm<sup>-1</sup> were observed after NO + O<sub>2</sub> adsorption on all samples. Based on literature studies, the two bands at about 1583 and 1281 cm<sup>-1</sup> were assigned to nitrate species, while the band at about 1609 cm<sup>-1</sup> was attributed to adsorbed NO<sub>2</sub> species [56–58], and the band at 1543 cm<sup>-1</sup> could also be assigned to NO<sub>2</sub>-containing species, like nitrito (O-bound NO<sub>2</sub>) and nitro (NO<sub>3</sub>) species [59].

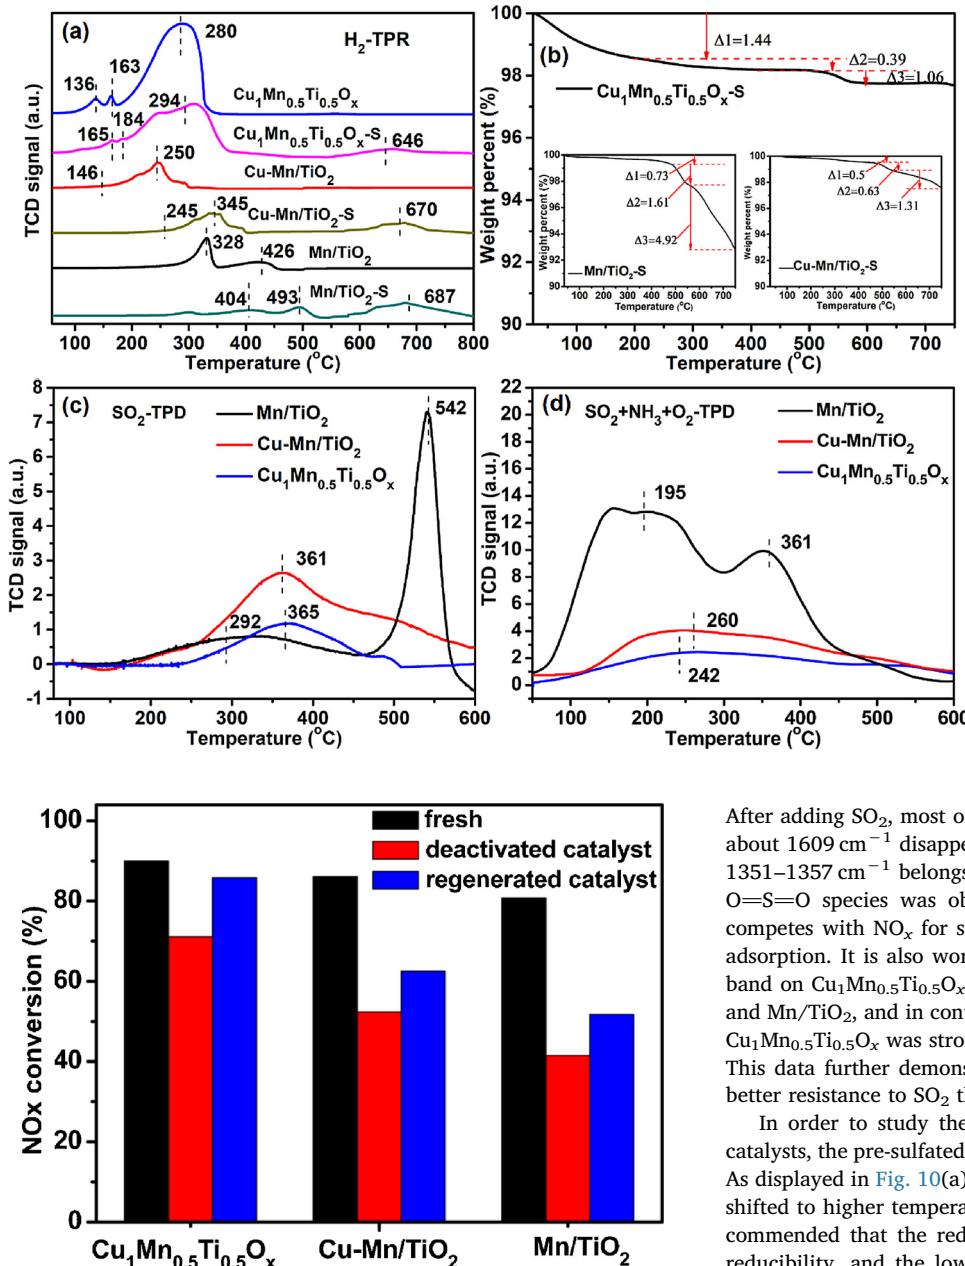

Fig. 11. NO<sub>x</sub> conversions of fresh, deactivated and regenerated catalysts treated by thermal regeneration. Reaction conditions: [NO<sub>x</sub>] = [NH<sub>3</sub>] = 500 ppm, [O<sub>2</sub>] = 5%, [H<sub>2</sub>O] = 5%, [SO<sub>2</sub>] = 100 ppm, balance Ar, total flow rate = 200 mL/min, GHSV = 60,000 h<sup>-1</sup>, testing temperature = 200 °C, catalyst 0.15 g.

The enhancement role of copper oxide can be interpreted that NO could be oxidized to NO<sub>2</sub> easily at low temperatures. To better explain the formation of NO<sub>2</sub> in the mechanism scheme, NO oxidation experiment was conducted. The inlet gas contained 500 ppm NO<sub>x</sub> (about 455 ppm NO, and 45 ppm NO<sub>2</sub>), and 5% O<sub>2</sub> with Ar as balance. At 200 °C, the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> was exposed to the gas for 140 min, the concentration of each component was monitored. Fig. S4 shows that the concentration of NO<sub>2</sub> increased from 45 ppm to 152 ppm, indicating that NO was oxidized to NO<sub>2</sub> in the presence of catalyst. This is conducive to the formation of ammonium nitrite, which promotes the occurrence of “fast-SCR”.

In addition, the interactions between SO<sub>2</sub> and NO<sub>x</sub> were also investigated by comparing the in situ DRIFT spectra taken during catalyst exposure to NO<sub>x</sub> and SO<sub>2</sub> co-adsorption with NO<sub>x</sub>, as shown in Fig. 9.

After adding SO<sub>2</sub>, most of the bands for NO<sub>x</sub> species except the one at about 1609 cm<sup>-1</sup> disappeared, and in the meantime, the new band at 1351–1357 cm<sup>-1</sup> belongs to the asymmetric stretching frequencies of O=S=O species was observed. The results again proved that SO<sub>2</sub> competes with NO<sub>x</sub> for surface adsorption sites, resulting in less NO<sub>x</sub> adsorption. It is also worth noting that the intensity of sulfur species band on Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> was much weaker than that on Cu-Mn/TiO<sub>2</sub> and Mn/TiO<sub>2</sub>, and in contrary the intensity of the NO<sub>x</sub> species band on Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> was stronger than that on Cu-Mn/TiO<sub>2</sub> and Mn/TiO<sub>2</sub>. This data further demonstrated that the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst has better resistance to SO<sub>2</sub> than other catalysts.

In order to study the influence of SO<sub>2</sub> on the redox property of catalysts, the pre-sulfated and fresh catalysts were analyzed by H<sub>2</sub>-TPR. As displayed in Fig. 10(a), the reduction peaks of pre-sulfated catalysts shifted to higher temperatures than the fresh catalysts. It has been recommended that the reduction peak temperature is an indication of reducibility, and the lower reduction temperature represents greater reducibility. In addition, the reduction peak area of all the samples reduced, indicating that SO<sub>2</sub> had negative effect on the reducibility of catalysts. For Mn/TiO<sub>2</sub> catalyst, the two reduction peaks located at 328 and 426 °C were greatly shifted to 404 and 493 °C. These data suggested that the addition of Cu can promote the SO<sub>2</sub> resistance of Mn-based SCR catalyst. For the Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts obtained from LDHs precursors, the reduction peak temperatures were still very low even after SO<sub>2</sub> pre-sulfation, which only slightly increased from 136, 163, and 280 °C to 165, 184, and 294 °C. Compared with Mn/TiO<sub>2</sub> and Cu-Mn/TiO<sub>2</sub>, the reduction peak for Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> was somehow stronger and the peak temperature was still very low.

In addition, a high temperature H<sub>2</sub> consumption peak at 646–687 °C was observed for all pre-sulfated Mn/TiO<sub>2</sub>, Cu-Mn/TiO<sub>2</sub>, and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalysts. This peak was absent with all fresh catalysts, confirming that it was due to the reduction of sulfates species. The TCD signal at high temperature (646–687 °C) assigned to SO<sub>2</sub> and H<sub>2</sub>S further supported that sulfur is mainly stored as either sulfates or surface SO<sub>2</sub> groups, consistent with literature reports by Zhang et al. [57] and Wijayanti et al. [60]. The H<sub>2</sub> consumption of Mn/TiO<sub>2</sub>-S, Cu-Mn/TiO<sub>2</sub>-S, and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>-S were also quantified, which followed the

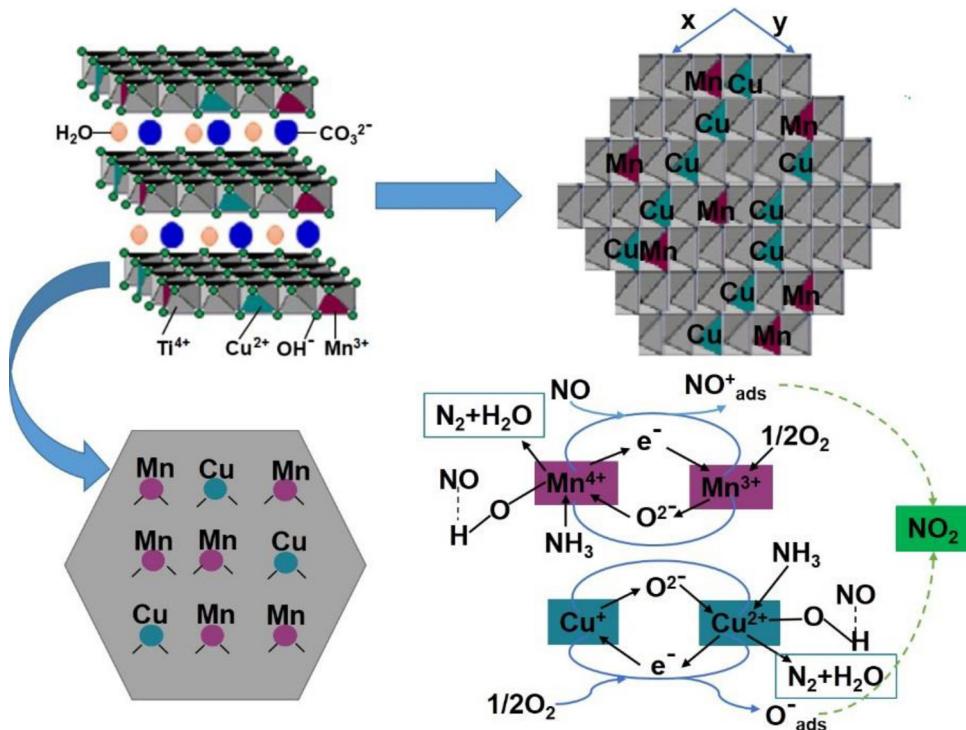

Fig. 12. Schematic illustration of the preparation process of CuMnTiO<sub>x</sub>, and a redox catalytic cycle of the low-temperature NH<sub>3</sub>-SCR reactions over CuMnTiO<sub>x</sub> catalysts.

order of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>-S (0.81 mmol/g) > Cu-Mn/TiO<sub>2</sub>-S (0.16 mmol/g) > Mn/TiO<sub>2</sub>-S (0.1 mmol/g). Thus, it can be concluded that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> catalyst has the best SO<sub>2</sub> resistance among all studied catalysts.

To explain this, TGA test was used to analyze the thermal stability of pre-sulfated Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub> and Mn/TiO<sub>2</sub>. Fig. 10(b) shows that the weight loss of the pre-sulfated samples was in three steps. The step 1 (26–200 °C) is mainly due to the desorption of water adsorbed on samples [49,61]. The weight loss in step 2 (200–550 °C) was due to the decomposition of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and/or NH<sub>4</sub>HSO<sub>4</sub> [31], and the weight loss in step 3 (550–800 °C) corresponds to Ti(SO<sub>4</sub>)<sub>2</sub>, Mn (SO<sub>4</sub>)<sub>2</sub>, and/or CuSO<sub>4</sub>. For the pre-sulfated Mn/TiO<sub>2</sub>, it showed a weight loss of 1.61 wt% and 4.92 wt% in step 2 and step 3, respectively. After adding Cu to the Mn-based catalyst, the weight loss for Cu-Mn/TiO<sub>2</sub> and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> became much less, which was 0.63 wt% and 0.39 wt% in step 2, and 1.31 wt% and 1.06 wt% in step 3, respectively. The results further demonstrated that less sulfate species was deposited on the surface of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>. The above results explains why Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has better activity even in the presence of SO<sub>2</sub>.

In order to explain the influence of SO<sub>2</sub>, SO<sub>2</sub>-TPD analyses were performed with Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> after exposure to 5000 ppm SO<sub>2</sub> at 80 °C for 1 h, as shown in Fig. 10(c). For Mn/TiO<sub>2</sub>, two SO<sub>2</sub> desorption peaks were observed at 292 and 542 °C. However, only one major SO<sub>2</sub> desorption peak appeared at 361 °C for Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> and 365 °C for Cu-Mn/TiO<sub>2</sub>, which was due to the decomposition of sulfate species [62,63]. The SO<sub>2</sub>-TPD peak of Mn/TiO<sub>2</sub> is much larger than that for Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, indicating Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has excellent SO<sub>2</sub>-resistant capacity. The deactivation of catalysts can be attributed to the sulfate species formation, which is consistent with the TGA analysis. In addition, the SO<sub>2</sub>-desorption temperature of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> is much lower than that of Mn/TiO<sub>2</sub>, and this will be very beneficial for the catalyst regeneration process.

In addition, the SO<sub>2</sub> + NH<sub>3</sub> + O<sub>2</sub>-TPD analyses of samples were used to clarify sulfate species. Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> were exposed to 2500 ppm SO<sub>2</sub> and 2500 ppm NH<sub>3</sub> in the presence of 5% O<sub>2</sub> at 80 °C for 1 h, and all SO<sub>2</sub> + NH<sub>3</sub> + O<sub>2</sub>-TPD results were shown

in Fig. 10(d). For Mn/TiO<sub>2</sub>, there are two desorption peaks at about 195 and 361 °C, which are attributed to the decomposition of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>/NH<sub>4</sub>HSO<sub>4</sub> and sulfate species. For Cu-Mn/TiO<sub>2</sub> and Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, only one wide desorption peak (about 260 and 242 °C) attributable to (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>/NH<sub>4</sub>HSO<sub>4</sub> and sulfate species appeared, respectively. Obviously, it can be seen that the desorption peak of Mn/TiO<sub>2</sub> is much stronger than Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>. Combining the in situ DRFT, SO<sub>2</sub>-TPD, TGA, and SO<sub>2</sub> + NH<sub>3</sub> + O<sub>2</sub>-TPD analyses, we can conclude that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has less (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>/NH<sub>4</sub>HSO<sub>4</sub> and sulfate species formation, indicating Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has superior SO<sub>2</sub> resistance.

Fig. 11 shows the NO<sub>x</sub> conversion of the deactivated catalysts after thermal regeneration. The NO<sub>x</sub> conversion of fresh Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> at 200 °C was 90%, 86.1%, and 80.7%, respectively. After 12 h of operation in the presence of 100 ppm SO<sub>2</sub>, the NO<sub>x</sub> conversions of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> catalysts decreased to 71.1%, 52.3%, and 41.5%, respectively. After thermal regeneration at 400 °C in air, the NO<sub>x</sub> conversion of Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub>, Cu-Mn/TiO<sub>2</sub>, and Mn/TiO<sub>2</sub> was recovered to 85.8%, 62.6%, and 51.8%, respectively. These results clearly indicated that Cu<sub>1</sub>Mn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>x</sub> has much better regenerability and greater potential for practical applications than other catalysts.

### 3.2.3. Mechanism study

In all, the high activity of CuMnTiO<sub>x</sub> catalyst for NH<sub>3</sub>-SCR at low-temperature could be attributed to high dispersion of manganese oxides and copper oxide with a high SSA, as well as the abundance of acid sites, etc. The NO oxidation reaction could be enhanced by the electron transferring, as shown in the following Eqs. (3)–(5) [64–67]. In addition, adding Cu can increase the amount of acid sites and enhance the SO<sub>2</sub> resistance of the Mn-based NH<sub>3</sub>-SCR catalysts. Based on the all the above results, a redox cycle for the NH<sub>3</sub>-SCR reaction at low temperatures over this novel CuMnTiO<sub>x</sub> catalyst can be proposed, as described in Fig. 12. The NH<sub>3</sub>-SCR reaction mechanism over CuMnTiO<sub>x</sub> could be explained by the E-R mechanism and L-H mechanism [68–70]. The coordinated NH<sub>3</sub> on the Lewis acid sites and the NH<sub>4</sub><sup>+</sup> on the Brønsted acid sites can react with gaseous NO (E-R mechanism) and the adsorbed

NO (L-H mechanism) over the  $\text{CuMnTiO}_x$  catalyst. In E-R mechanism, the absorbed  $\text{NH}_3$  species is converted to  $\text{NH}_2$  species, and then reacts with gaseous NO to form highly active  $\text{NH}_4\text{NO}_2/\text{NH}_2\text{NO}$  intermediate. After that,  $\text{NH}_4\text{NO}_2/\text{NH}_2\text{NO}$  is unstable and decompose rapidly into  $\text{N}_2$  and  $\text{H}_2\text{O}$ . While in the L-H mechanism, the  $\text{NH}_3$ -SCR reaction occurs between adsorbed  $\text{NH}_3$  species and adsorbed NO species.

#### 4. Conclusions

We designed a series of novel low-temperature  $\text{NH}_3$ -SCR catalysts  $\text{Cu}_w\text{Mn}_y\text{Ti}_{1-y}\text{O}_x$  containing  $\text{CuO}$  and  $\text{MnO}_x$  as active components and  $\text{TiO}_2$  as support from  $\text{Cu}_w\text{Mn}_y\text{Ti}_{1-y}\text{CO}_3$  LDHs precursors. The optimal sample  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  displayed a high De- $\text{NO}_x$  efficiency of 90% at 200 °C, higher than that for 20 wt% Mn/ $\text{TiO}_2$  (80.7%), 10 wt% Cu-10 wt% Mn/ $\text{TiO}_2$  (86.1%), 20 wt% Cu-20 wt% Mn/ $\text{TiO}_2$  (80.2%), and 40 wt% Cu-20 wt% Mn/ $\text{TiO}_2$  (60.3%). XRD, HR-TEM, and XPS analyses showed that the  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  sample contains highly dispersed  $\text{MnO}_2$  and  $\text{CuO}$  phases, which may be partly responsible for its good performance.  $\text{NH}_3$ -TPD, Py-FTIR, in situ DRIFT, and  $\text{H}_2$ -TPR results suggested that  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  possesses more acid sites and surface active species than other samples studied in this work. In addition,  $\text{Cu}_1\text{Mn}_{0.5}\text{Ti}_{0.5}\text{O}_x$  has excellent resistance to  $\text{SO}_2$  and  $\text{H}_2\text{O}$ , and its aged sample has better regenerability, suggesting a greater potential for practical applications.
